Harden SSL TLS [Mac/Win]

What's New In?

There is no longer any reason why you would want to use TLS, and it is highly recommended that you disable TLS and ONLY use SSLv3 if you absolutely need to. It will be easier to perform necessary retro-porting of old SSLv3 apps to TLS. I do not recommend any SSLv3 because of the now very well known Heartbleed vulnerability. It would be virtually impossible to find any SSLv3 client that is actually vulnerable. It is therefore recommended that you upgrade all apps that use SSLv3 as soon as possible. Obviously you can also configure your applications to only use certain protocols. However, many applications do not support ciphers that are not listed in the protocols they use. It is very difficult to protect against many applications and scenarios if you allow them to use all ciphers. Harden SSL/TLS allows you to set your SSL policies locally and remotely and denying certain ciphers/ashes or complete ciphersuites. This tool specific allows setting policies with regards to what ciphers and protocols are available to applications that use SCHANNEL crypto interface. A lot of windows applications do use this interface, for instance Google Chrome. By changing the settings you can indirectly control what ciphers these applications are allowed to use. Description: There is no longer any reason why you would want to use TLS, and it is highly recommended that you disable TLS and ONLY use SSLv3 if you absolutely need to.
