A: Ok, here's a few tips: Place a modulo operator (//) immediately before each string that you want to be broken into its constituent characters. This modulo operator will match and consume one character at a time. This is effectively "padding" your strings to make them easy to break into their characters. Put all of your strings into a string and use the function String.split(String, int) with as many delimiters as you think would be the optimal amount. In my opinion, if you are just doing a quick check of your script, you may even try using String.substring(int) and trim() to shorten your script a little bit. Just a note, though, in your example, you actually do not need to run String.substring(int) to get the value after the 5th character. You can simply just run String.substring(4) and it will return the string from the 4th character onward. As a final note, for the sake of simplifying your script a little bit, you may want to consider only executing the part of your script that needs to be executed. As you can see in the second example, I'm doing this by simply creating a collection of all the strings, calling the function String.split(), then only calling the last string in my collection that has as many delimiters as I think is necessary. Haider Zaman Haider Zaman (born 20 January 1992) is a Pakistani cricketer. He made his first-class debut for Sialkot in the 2011–12 Quaid-e-Azam Trophy on 28 October 2011. I am pretty new to programming, and I am having trouble finding the best way to do something I have seen done in other languages, so I thought I would ask here: I have a class called Vehicle, and I have a class called Car, and a class called Bike. I would like to have a shared vector of Vehicles, and within each of those classes I need to know which vehicles they are associated with. How can I best accomplish this 54b84cb42d
